NPL with Pytorch Tutorial 0

Python Basics

About this tutorial

- 11 parts (ideally)
 - Book
 - Additional Material (if necessary)
- Each time:
 - ➤ During the tutorial: learn something new (チュートリアルで:新しい内容)
 - ➤ At home: Do a programming exercise (宿題:プログラミング演習)
- ❖ Working in pair is encouraged (ペアで話し合いをする)

- If English is difficult for you, you don't need to attend
 - ➤ However, I encourage to do the exercises at home if you have time

Plan for Today

Python Basics

Slides and examples borrowed/adapted from:

Kevin Duh: http://cs.jhu.edu/~kevinduh/index.html

Graham Neubig: http://www.phontron.com/index.php?lang=en

(Both are great NLP researchers and I recommend everybody to read their papers)

What is NLP?

Natural Language Processing (NLP) studies how computers can interpret and manipulate text

Intro

For writing programs for NLP, people often use Python

What is python?

- general-purpose, high-level scripting language
- Used in a variety of purposes: e.g. networking, web applications
- Most popular in the scientific community

Pros vs Cons

Pros

Easy to understand (similar to English)

Works across systems (Windows, Mac, Linux)

Object Oriented

Great standard and additional libraries

Cons

Python can be slow

Setting up your python environment

If you are on Linux or Mac

Open the "terminal"

If you are on Windows

Install cygwin

Or use "ssh" to login to the one of the Linux servers

Install Software (if necessary)

- 1) Python: the programming language
- 2) A text editor (vim, emacs, etc.)
- 3) IDE: PyCharm, Sublime, VS Code

Download the Tutorial Files from Github

Use the git "clone" command

git clone https://github.com/lis-kp/tutorial

1) Python on terminal

Go to terminal:

Type **python**

Type print("hello!")

Type **2 + 2**

```
[>>> print("hello!")
hello!
[>>> 2 + 2
4
```

2) Using Vim

Open vim:

```
$ vi test.txt
```

Press "i" to start input

Write "test"

Press "esc"

Type ":wq" to save and quit (":w" is save; ":q" is quit)

3) Using an IDE

❖ To write longer programs, people often use IDEs

Pycharm, Sublime, VSCode

IDEs include features like as code completion and syntax checking

If you choose to just use a text editor, you can run your program from terminal by using the command:

python <filename.py>

Hello World!

- 1) Open hello.py in an editor (e.g. vim)
- 2) Type the following program print("Hello World!")
- 3) Run the program

```
[lis@fermat:~$ python hello.py
Hello World!
```

Main data types used

Strings: "hello", "goodbye"

Integers: -1,0,1,3

Floats: -4.2, 0.0, 3.14

```
my_int = 4
my_float = 2.5
my_string = "hello"

print('string: {:s}\tfloat: {:f}\tint: {:d}'.format(my_string, my_float, my_int))
```

Main data types used

Strings: "hello", "goodbye"

Integers: -1,0,1,3

Floats: -4.2, 0.0, 3.14

```
my_int = 4
my_float = 2.5
my_string = "hello"

print('string: {:s}\tfloat: {:f}\tint: {:d}'.format(my_string, my_float, my_int))
```

string: hello float: 2.500000 int: 4

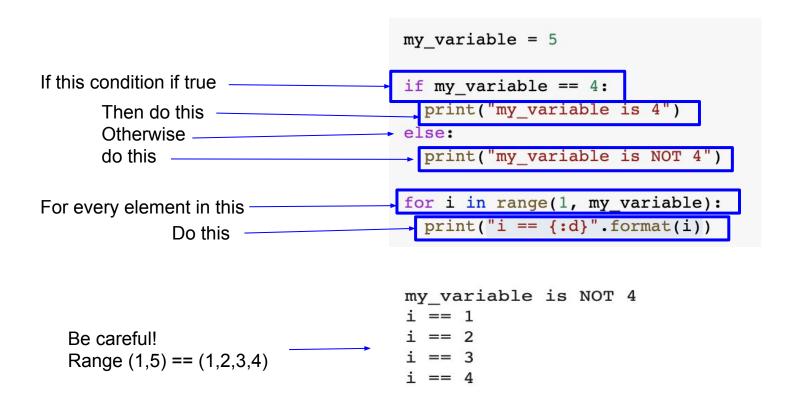

```
if this condition if true

if my_variable = 4:

Then do this
Otherwise
do this

for i in range(1, my_variable):
    print("i == {:d}".format(i))
```

```
my variable = 5
If this condition if true ———
                                   if my variable == 4:
                                    print("my variable is 4")
      Then do this ————
                                   else:
     Otherwise _____
      do this ————
                                     print("my variable is NOT 4")
                                   for i in range(1, my_variable):
For every element in this —
                                     print("i == {:d}".format(i))
            Do this —
                                   my variable is NOT 4
```

Arrays (or "lists" in Python)

```
my_list = [1,2,4,8,16]  Make a list with 5 elements
                                    Add one or more elements to
my list.append(32) ←
                                     the end of the list
print(len(my list)) <--</pre>
                                     Print the length of the list
print(my list[3])
print("")
                                     Print the 4th element
for value in my list:
  print(value)
                                     Loop through and print
                                     every element of the list
```

Arrays (or "lists" in Python)

Index is an integer, starting at 0

```
my_list = [1,2,4,8,16]  Make a list with 5 elements
my list.append(32) ←
print(len(my list)) 
print(my list[3])
print("")
for value in my list: -
  print(value)
```

Add one or more elements to the end of the list

Print the length of the list

Print the 4th element

Loop through and print every element of the list

<u> </u>	
Index	Value
0	1
1	2
2	4
3	8
4	16

Arrays (or "lists" in Python)

Index is an integer, starting at 0

```
my list = [1,2,4,8,16]
my list.append(32) ←
print(len(my list)) 
print(my list[3])
print("")
for value in my list: -
  print(value)
 6
```

—— Make a list with 5 elements

Add one or more elements to the end of the list

Print the length of the list

Print the 4th element

Loop through and print every element of the list

Index	Value
0	1
1	2
2	4
3	8
4	16

Sorting Lists

```
random_list = [3,12,5,6]
sorted_list = sorted(random_list) ------ sorted function lets you sort a list
print(sorted_list)
```

Sorting Lists

```
random_list = [3,12,5,6]
sorted_list = sorted(random_list) ----- sorted function lets you sort a list
print(sorted_list)
```

[3, 5, 6, 12]

Maps (or "dictionaries" in Python)

```
my dict = {"olivia": 22, "maria": 30, "sophia": 18, "emily": 45}
                                       Add a new entry
my dict["rachel"] = 15
                                       Print size
print(len(my dict))
print(my dict["emily"])
                                       Print one entry
print("")
                                              Check if a key exists
if "elizabeth" in my dict:
  print("elizabeth exists in my dict")
print("my dict sorted by key")
                                                     Print key/value
for key, value in sorted(my dict.items()):
  print('{:s} --> {:d}'.format(key, value))
                                                     pairs by key order
print("")
print("my dict sorted by value")
for key, value in sorted(my dict.items(), key=lambda x:x[1]):
  print('{:s} --> {:d}'.format(key, value))
```

Key	Value
olivia	22
maria	30
sophia	18
emily	45

Print key/value pairs by value order

Maps (or "dictionaries" in Python)

```
my dict = {"olivia": 22, "maria": 30, "sophia": 18, "emily": 45}
my dict["rachel"] = 15
print(len(my dict))
print(my dict["emily"])
print("")
if "elizabeth" in my dict:
  print("elizabeth exists in my dict")
print("my dict sorted by key")
for key, value in sorted(my dict.items()):
  print('{:s} --> {:d}'.format(key, value))
print("")
print("my dict sorted by value")
for key, value in sorted(my dict.items(), key=lambda x:x[1]):
  print('{:s} --> {:d}'.format(key, value))
 45
 my dict sorted by key
 emily --> 45
 maria --> 30
 olivia --> 22
 rachel --> 15
 sophia --> 18
 my dict sorted by value
 rachel --> 15
 sophia --> 18
 olivia --> 22
 maria --> 30
```

emily --> 45

More on lists and dictionaries

```
my list = [1,2,"3","four", "four"]
                                                                Lists and dictionaries do not have a
my_set = set(my_list) 
                                                                fixed type: can contain anything
my_dict = {"olivia": 22, "maria": 30, "sophia": 18, "emily": 45}
print(my list)
                                      sets will remove duplicates: only one copy of "four"
print(my set)
print("")
for key, value in sorted(my dict.items()):
  print('{:s} --> {:d}'.format(key, value))
 [1, 2, '3', 'four', 'four']
 {'3', 1, 2, 'four'}
 emily --> 45
 maria --> 30
 olivia --> 22
 sophia --> 18
```

Splitting and joining strings

In NLP: often split sentences into words

```
sentence = "this is a book"
words = sentence.split(" ")

for word in words:
    print(word)

print("")
print("")
print(" ||| ".join(words))

Combine the array into a single string, separating with " ||| "
```

Splitting and joining strings

In NLP: often split sentences into words

```
sentence = "this is a book"
words = sentence.split(" ")

for word in words:
    print(word)

print("")
print("")
print(" | | | ".join(words))

Combine the array into a single string, separating with " || "
```

```
this
is
a
book
this ||| is ||| a ||| book
```

More string functions

```
my string1 = "book"
                                         Convert string to uppercase
print(my string.upper())
my string2 = "JAPAN"
                                         Convert string to lowercase
print(my_string.lower())
print("")
                                                    Checks if string starts with "b"
if my string1.startswith("b"):
 print("my string1 starts with \"b\"")
else:
 print("my string1 does NOT starts with \"b\"")
                                                       Checks if string ends with "S"
if my string2.endswith("S"):
 print("my string2 ends with \"S\"")
else:
 print("my string2 does NOT end with \"S\"")
print("")
mystring3 = " desk "
                                                  Delete the whitespaces
print(mystring3.strip())
```

More string functions

```
my string1 = "book"
print(my string.upper())
my string2 = "JAPAN"
print(my string.lower())
print("")
if my string1.startswith("b"):
  print("my string1 starts with \"b\"")
else:
  print("my string1 does NOT starts with \"b\"")
if my string2.endswith("S"):
  print("my string2 ends with \"S\"")
else:
  print("my string2 does NOT end with \"S\"")
print("")
mystring3 = " desk "
print(mystring3.strip())
```

```
HELLO
hello
my_string1 starts with "b"
my_string2 does NOT end with "S"
```

desk

Functions

Functions take an **input**, **transform** the input, and **return** and output

```
def mult_and_abs(x, y):
    z = x * y

if z >= 0:
    return z
else:
    return z * -1

print(mult_and_abs(-3, 2))

Call mult_and_abs takes "x" and "y"
    as input

Multiplies x and y together and return
    the absolute value

Call mult_and_abs with x=-3 and y=2
```

6

Using command line arguments/ Reading files

\$ python my_program.py test.txt

Testing your code

Write code to test each function

Test several cases

```
def test_mult_and_abs():
    assert(mult_and_abs(-3,2) == 6), "Error"
    return "Test passed!"

print(test_mult_and_abs())
```

Test passed!

Practice Exercise

Practice Exercise

Make a program that counts the frequency of words in a file

Test it on test/00-input.txt, test/00-answer.txt

Run the program on the file data/

Report:

The number of unique words

The frequency of each word

Pseudo-code

create a dictionary *counts*

open a file

for each line in the file
split line into words

for w in words

if w exists in counts, add 1 to counts[w]

create a map to hold counts

print key, value of *counts*

else set counts[w] = 1

For next week:

Try to practice the examples

Try to solve the exercise
